

PROJECT TITLE: IMPLEMENT CLIENT SCRIPT & UI POLICY (INCIDENT)

1. Project Overview & Introduction

1.1 Introduction to the Project

Modern IT service management requires fast, accurate, and automated incident handling. In ServiceNow, an Incident represents an unplanned interruption to an IT service or a reduction in the quality of service. To ensure data integrity, streamline user data entry, and enforce business rules directly on the client side (browser), organizations implement **Client Scripts** and **UI Policies**.

1.2 Purpose of Brainstorming

This brainstorming document serves as the foundational ideation phase for our Naan Mudhalvan project group. The core objective of this session was to identify current inefficiencies in standard incident creation forms, evaluate technical requirements, and outline the precise implementation strategy using the ServiceNow Developer instance.

2. Problem Identification & Business Challenges

2.1 Current Pain Points in Incident Management

During our initial team discussions, we identified several recurring issues faced by service desk agents and end-users while logging incidents in standard ITSM platforms:

- **Lack of Real-Time Validation:** Users frequently submit tickets with incomplete details, missing mandatory descriptions, or incorrect categorization, leading to delayed resolution times.
- **Static Form Behavior:** Standard forms display all fields simultaneously, overwhelming users with irrelevant inputs and cluttering the user interface.
- **Manual Urgency & Priority Mismatch:** Users often misjudge the urgency or impact levels, resulting in improperly prioritized tickets that disrupt IT support workflows.

2.2 Impact of These Challenges

- Increased administrative overhead for IT support teams.
- Slower Mean Time to Resolution (MTTR).
- Reduced data quality and inaccurate reporting metrics within the ServiceNow database.

3. Proposed Technical Solutions

To mitigate the challenges identified above, our team brainstormed and finalized the deployment of specific ServiceNow automation tools:

3.1 UI Policy Implementation

- **Dynamic Field Visibility:** Automatically display or hide specific fields based on user selection (e.g., revealing specific error logs only when a particular Category is chosen).
- **Mandatory Field Enforcement:** Dynamically force fields like "Short Description" or "Urgency" to become mandatory only under specific conditions without writing complex server-side code.
- **Read-Only States:** Protect critical configuration fields from unauthorized modification at the form level.

3.2 Client Script Implementation

- **onChange Scripts:** Trigger instant field validation the moment a user modifies a specific field value (e.g., checking date logic or auto-populating related fields).
- **onLoad Scripts:** Modify form layouts, display welcome alert banners, or set default field values automatically when the incident form loads for the user.
- **onSubmit Scripts:** Prevent form submission if validation rules fail (e.g., verifying that mandatory fields contain valid formats before saving to the database).

4. Project Scope & Team Work Distribution

To execute this project efficiently, our team (Led by Annesia J, with members Subitha P, Vanapetchi M, P Govika, and Arisha Ponkumar Nadar) brainstormed and distributed the workload across multiple milestones:

- **Module 1: UI Policy Creation & Urgency Configuration**
 - Focuses on building dynamic rules and managing field behaviors.
- **Module 2: Client Script Development (onChange, onLoad, onSubmit)**
 - Focuses on writing JavaScript functions within the ServiceNow IDE to execute client-side logic.
- **Module 3: Comprehensive Testing & Validation**
 - Systematic execution of test cases (mandatory enforcement, reverse condition tests, form-based updates, and list-edit blocking) to ensure robust performance.

5. Expected Outcomes & Conclusion

5.1 Expected Benefits

- **Enhanced User Experience (UX):** A cleaner, more responsive, and intuitive incident creation interface.
- **Data Accuracy:** Elimination of human errors through automated validations before data hits the server.
- **Operational Efficiency:** Faster incident logging and streamlined workflows for IT agents.

5.2 Conclusion

The brainstorming session successfully established the blueprint for our ServiceNow project. By combining UI Policies for layout control and Client Scripts for behavior validation, our team is well-prepared to proceed to the **Define Problem** and **Empathy Map** phases of the Naan Mudhalvan documentation pipeline.
